# The concept model of emission from a livestock building

The diagram illustrates the concept model of emission from a livestock building. It shows a cross-section of a building with a gabled roof. Air flow is indicated by arrows: a yellow arrow pointing up from the roof, a blue arrow pointing right from the left wall, a blue arrow pointing left from the right wall, and a red arrow pointing left from the floor. Concentration labels are placed near these flows:  $C_a$  near the roof,  $C_{a,r}$  near the right wall,  $C_{of}$  near the left wall,  $C_{sl,a}$  near the floor,  $C_{sf}$  near the animals, and  $C_{sl,s}$  near the floor. A yellow curved arrow indicates air flow from the roof to the right wall, and a red curved arrow indicates air flow from the floor to the left wall. Three orange pigs are shown on the floor. The formula  $E_{total} = \sum_{i=1}^m E_i$  is shown in the top right corner.

$E_{total} = \sum_{i=1}^m E_i$

Guoqiang Zhang

## Emission & emission coefficient

The core model is a model of convective mass transfer. Determination of the convective mass transfer coefficient is essential for modelling  $\text{NH}_3$  release. This coefficient ranges from  $1.2 \times 10^{-4}$  to  $1.3 \times 10^{-6}$  m/s as investigated in laboratory and field experiments.

**Definitions of the emission coefficients:** overall emission coefficient; Gas phase convective mass transfer coefficient;

Aarhus University  
Department of Engineering

Guoqiang Zhang

## Emission & emission coefficient (2)

- It usually suffices to express emission coefficient as a function of air velocity at the manure surface and air or manure temperature.
- Determination of the gaseous  $\text{NH}_3$  concentration at the manure surface is also essential. This concentration can be calculated using some *sub-models*, which may include *Henry's constant*, *dissociation constant*, *pH*, manure production by animals,  $\text{NH}_3$  generation in manure and  $\text{NH}_3$  diffusion in manure.
- The Henry's constant found in a reviewed reports has different definitions and units. A standard Henry's constant is needed.

# Ammonia Kinetics in Solusion

*The form of ammonia that can be volatilized from a solution is free ammonia*

$$\sum NH_3 = NH_3 + NH_4^+$$

*where  $NH_3$  and  $NH_4^+$  are at equilibrium at all points in the liquid (effectively instantaneous)*

*The ammonia dissociation constant can be expressed as:*

$$K_d = \frac{NH_3 H^+}{NH_4}$$

Aarhus University  
Department of Engineering

Guoqiang Zhang

## Ammonia Kinetics in Solusion (2)

*The fraction of  $NH_3$  in manure is*

$$f = \frac{[NH_3]}{[\sum NH_3]}$$

*Since*

$$pH = -\log[H^+]$$

$$f = \frac{K_d 10^{pH}}{K_d 10^{pH} + 1}$$

Aarhus University  
Department of Engineering

Guoqiang Zhang

## Estimation of $K_d$ & $K_H$

**Dissociation constant for ammonia in water:**

$$K_d = 10^{-(0.0897 + 2729/T)}$$

where,  $T$  is the liquid temperature in  $^{\circ}\text{K}$

In liquid pig manure, it was found that the  $K_d$  is about one-fifth of the  $K_d$  in water (Zhang et al., 1994).

**Henry's law constant,  $K_H$ , at air-liquid surface:**

$$K_H = \frac{C_l}{C_g}$$

$$K_H = 1384 \times 1.053^{(293-T)}$$

Aarhus University  
Department of Engineering

Guoqiang Zhang

The equilibrium ratio of ammonia in the liquid phase and ammonia in the gas phase is often expressed as a **ratio of ammonia concentration and the partial pressure of the ammonia**, which is called the Henry coefficient ( $K_h$ ).

Again, by applying the ideal gas law at  $10^{\circ}\text{C}$ , this can be converted to the Henry constant. ( $H_{cc} = C_l/C_g = H_{cp}RT$  and here  $K_H = H_{cc}$ ;  $K_h = H_{cp}$ ).

The Henry coefficient, expressed in  $\text{g}\cdot\text{cm}^{-3}\text{ atm}^{-1}$ , was given by Hashimoto and Ludington (1971) as:

$$K_h = 1.013 \times (1.053)^{293-T}$$

This results in the following expression for Henry's constant:

$$K_H = 1384 \times 1.053^{(293-T)}$$

(Elzing & Monteny, 1997)

Guoqiang Zhang

## The Overall Mass Transfer Coefficient

### Emission flux $N$

$$N_g = k_g (C_{gb} - C_{gi})$$

$$N_l = k_l (C_{lb} - C_{li})$$

$$N_g = N_l$$

$$C_{gi} = C_{li} / K_H$$

Aarhus University  
 Department of Engineering

Guoqiang Zhang

These investigators considered mass transfer from a liquid to a gas to take place through two phases, one in the liquid and one in the gas. As with heat transfer, an overall mass transfer coefficient can be written:

$$\frac{1}{K_g} = \frac{1}{k_g} + \frac{1}{K_H k_l}$$

where the driving force analogous to temperature gradient is the component partial pressure gradient. Henry's law coefficient,  $K_H$ , is introduced to allow concentration gradients within the liquid to be replaced by their equivalent partial pressure gradients. The  $k_g$  relates to partial pressure and  $k_l$  relates to concentration. If the bulk fluids are well mixed, then essentially all resistance to mass transfer occurs within the two boundary layers each side of the interface. Under these conditions, Halsam et al. determined experimentally that:

$$k_g = f(v^{0.8}T^{-1.4})$$

$$k_l = g(T^4)$$

## The Boundary Layer Concept

The observation of decreasing region of influence of shear stress as the Reynolds number is increased led Ludwig Prandtl to the boundary-layer concept in 1904.

Boundary layer on a flat plate

Aarhus University  
Department of Engineering

Guoqiang Zhang

## The Boundary Layer Concept

The criterion for the type of boundary layer present is the magnitude of Reynolds number,  $Re_x$ , known as the local Reynolds number, based on the distance  $x$  from the leading edge.

$$Re \equiv \frac{xv\rho}{\mu}$$

- (a)  $Re_x < 2 \times 10^5$  the boundary layer is laminar
- (b)  $2 \times 10^5 < Re_x < 3 \times 10^6$  the boundary layer may be either laminar or turbulent
- (c)  $3 \times 10^6 < Re_x$  the boundary layer is turbulent

$\mu$  (dynamic viscosity) =  $1.82 \text{ (kg/m s)} \times 10^{-5}$  (at temperature  $20^\circ\text{C}$ )

Aarhus University  
Department of Engineering

Guoqiang Zhang

## The Boundary Layer Concept

For laminar flow:

$$\frac{k_c x}{D_{AB}} = Sh_x = 0.332 Re_x^{1/2} Sc^{1/3}$$

For turbulent flow:

$$\frac{k_c x}{D_{AB}} = Sh_x = 0.0292 Re_x^{4/5} Sc^{1/3}$$

where  $k_c$  is convective transfer coefficient at location  $x$

Aarhus University  
Department of Engineering

Guoqiang Zhang

## The Boundary Layer Concept

*For laminar flow:*

$$k_c = \frac{Sh_x}{x} D_{AB} = \frac{D_{AB}}{x} 0.332 \text{Re}_x^{1/2} Sc^{1/3}$$

*For turbulent flow:*

$$k_c = \frac{Sh_x}{x} D_{AB} = \frac{D_{AB}}{x} 0.0292 \text{Re}_x^{4/5} Sc^{1/3}$$

Aarhus University  
Department of Engineering

Guoqiang Zhang

## The Boundary Layer Concept

*For laminar flow:*

$$\begin{aligned} \overline{k_c} L &= \int_0^L \frac{Sh_x}{x} D_{AB} = \int_0^L \frac{D_{AB}}{x} 0.332 \text{Re}_x^{1/2} Sc^{1/3} \\ &= 0.664 D_{AB} Sc^{1/3} \text{Re}_L^{1/2} \end{aligned}$$

*For turbulent flow:*

$$\begin{aligned} \overline{k_c} L &= \int_0^L \frac{Sh_x}{x} D_{AB} = \int_0^L \frac{D_{AB}}{x} 0.0292 \text{Re}_x^{4/5} Sc^{1/3} \\ &= 0.0365 D_{AB} Sc^{1/3} \text{Re}_L^{4/5} \end{aligned}$$

where  $\overline{k_c}$  is average convective transfer coefficient along the length L

Aarhus University  
Department of Engineering

Guoqiang Zhang

## The Boundary Layer Concept

*For laminar flow:*

$$\frac{\overline{k_c} L}{D_{AB}} = Sh_L = 0.664 Sc^{1/3} Re_L^{1/2}$$

*For turbulent flow:*

$$\frac{\overline{k_c} L}{D_{AB}} = Sh_L = 0.0365 Sc^{1/3} Re_L^{4/5}$$

Aarhus University  
Department of Engineering

Guoqiang Zhang

## The Boundary Layer Concept

*Schmidt number,  $Sc$ , is the ratio of momentum diffusivity (viscosity) and mass diffusivity, and is used to characterize fluid flows in which there are simultaneous momentum and mass diffusion convection processes:*

$$Sc = \frac{\nu}{D} = \frac{\mu}{\rho D} = \frac{\text{viscous diffusion rate}}{\text{molecular(mass) diffusion rate}}$$

*Roughly, considering only nitrogen and oxygen and using 80%/20% instead of 78%/21%, the average molecular weight of air is about  $0.8 * 0.028 + 0.2 * 0.032 = 0.0288 \text{ kg/mol}$*

*Molar mass of  $NH_3 = 17.03052 \text{ g/mol}$*

Aarhus University  
Department of Engineering

Guoqiang Zhang

## The Boundary Layer Concept

The diffusivity (coefficient) of  $\text{NH}_3$  in air may be calculated by an empirical relation developed by Fuller et al. (1966):

$$D_{\text{NH}_3, \text{Air}} = \frac{10^{-7} (273.15 + T)^{1.75} \left( \frac{1}{M_{\text{NH}_3}} + \frac{1}{M_a} \right)^{1/2}}{P \left[ (\sum_{\text{NH}_3} v_i)^{1/3} + (\sum_a v_i)^{1/3} \right]^2}$$

where diffusion volumes for molecules of air,  $\sum_a v$ , and  $\text{NH}_3$   $\sum_{\text{NH}_3} v$  have a value of 20.1 and 14.9 respectively (Fuller et al., 1966).

Roughly, considering only nitrogen and oxygen and using 80%/20% instead of 78%/21%, the average molecular weight of air is about  $0.8 \times 0.028 + 0.2 \times 0.032 = 0.0288 \text{ kg/mol}$

Molar mass of  $\text{NH}_3 = 17.03052 \text{ g/mol}$

Aarhus University  
Department of Engineering

Guoqiang Zhang

## Exercise

- Liquid manure at temperature of  $10^\circ\text{C}$ , with pH of 8, TAN of 2.38 g/l, calculate the ammonia concentration at gas phase boundary layer in equilibrium condition.
- What about concentration level when manure temperature is  $25^\circ\text{C}$ ?
- Check the results when pH is varied to 7 in the case 1.

Aarhus University  
Department of Biosystems Engineering

Guoqiang Zhang

# Exercise

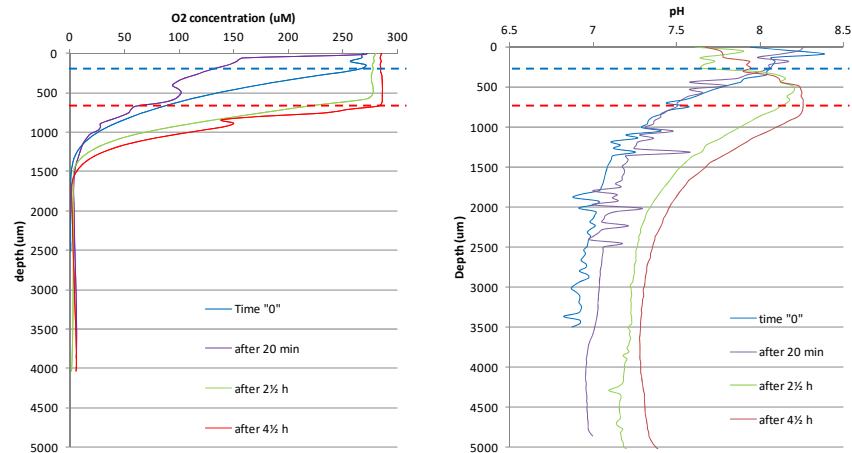

- Calculate Sh number for air in both laminar & turbulent flow at velocity of 0 - 0.5 m/s, over a emission surface length, L, of 6 m
- Calculate air phase mass transfer coefficient  $k_a$  for  $\text{NH}_3$  at temperature of 20 °C at the same air velocity ranges and different flow types
